

# UML

- UML is used as a graphical notation for describing programming concepts
- UML Stands for *Unified Modelling Language*
- It's not specific to Java
- For CSY2030 the main diagram is a CLASS DIAGRAM

# Why use UML?

- Other developers can quickly look at the diagram and understand how the program works
  - How the application is structured
  - The classes, methods and fields which are available
  - How those classes and methods can be used
  - How classes are related

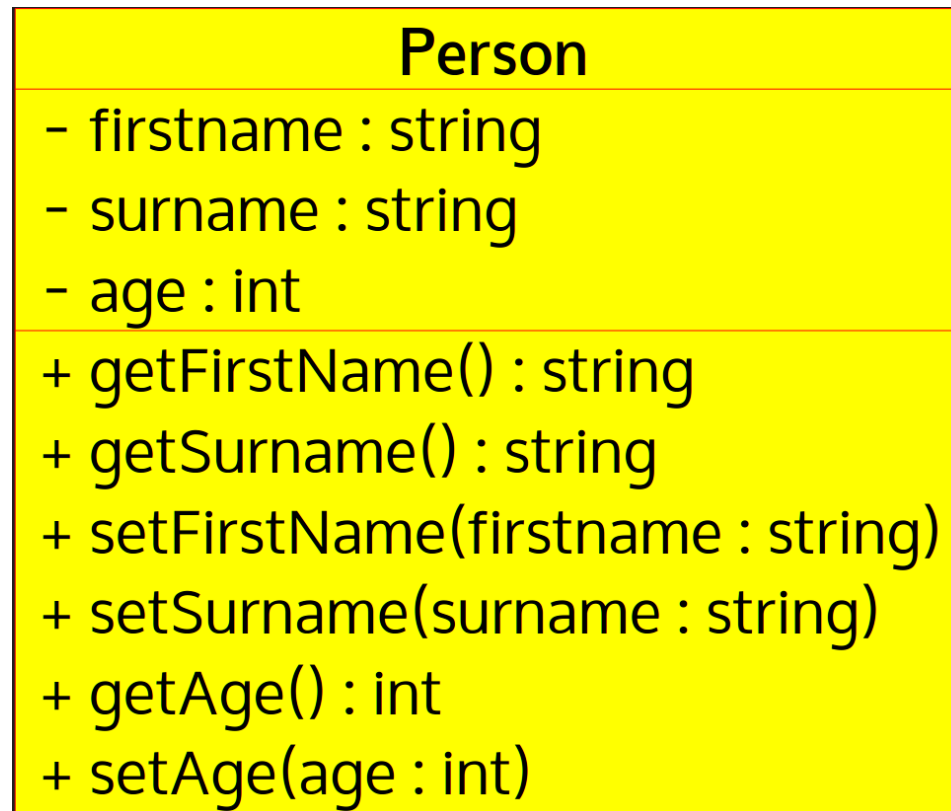

# Class diagrams

- Class diagrams are boxes with three parts

<b>Class Name</b>
Fields
Methods

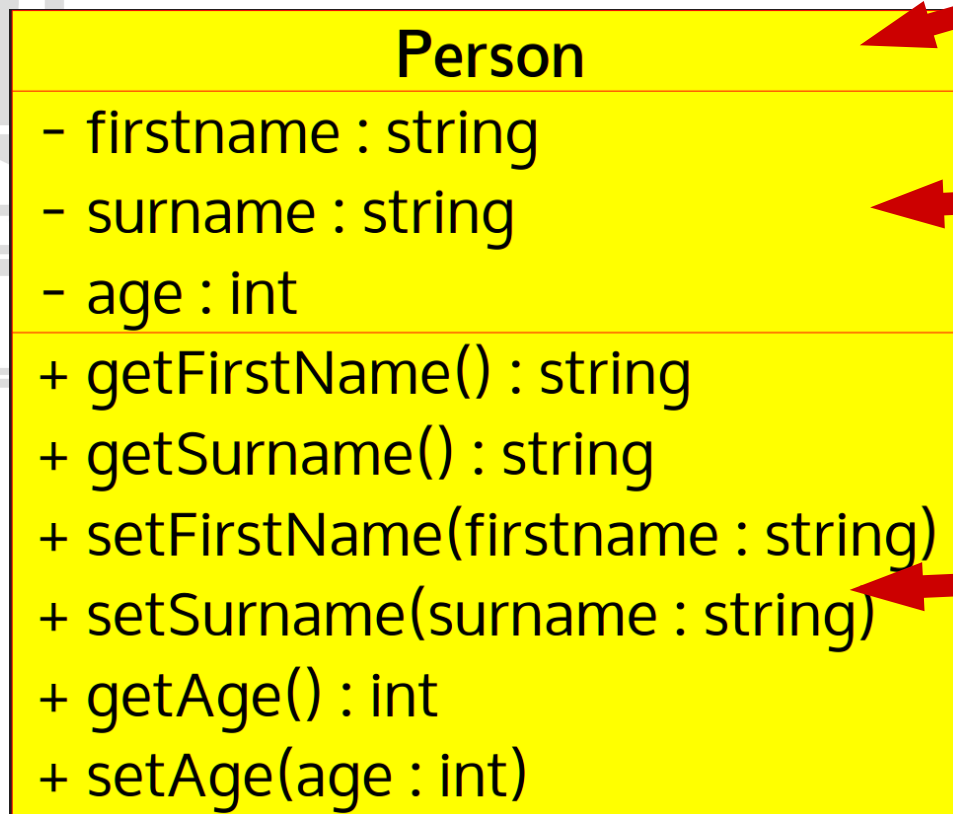

# Class Diagrams

- UML contains a diagram format for describing classes

# Class Diagram

- A class Diagram has 3 parts

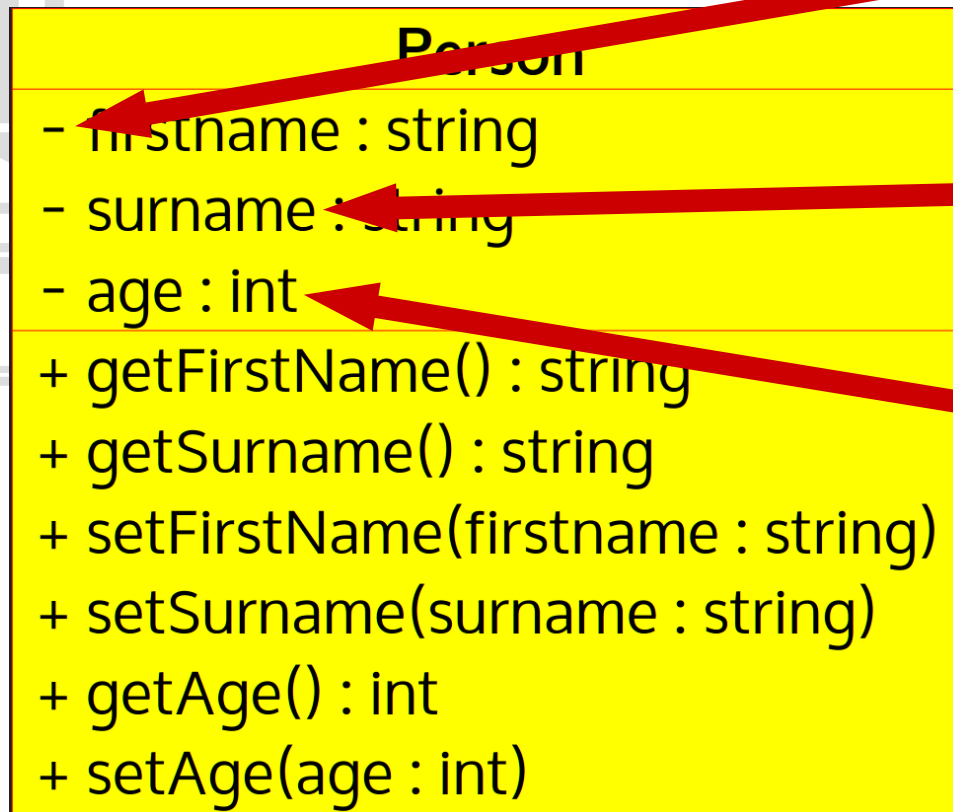

Class Name

Fields

Methods

# Class Diagram

- Class Diagram Fields

Visibility:  
- for private  
+ for public

Name

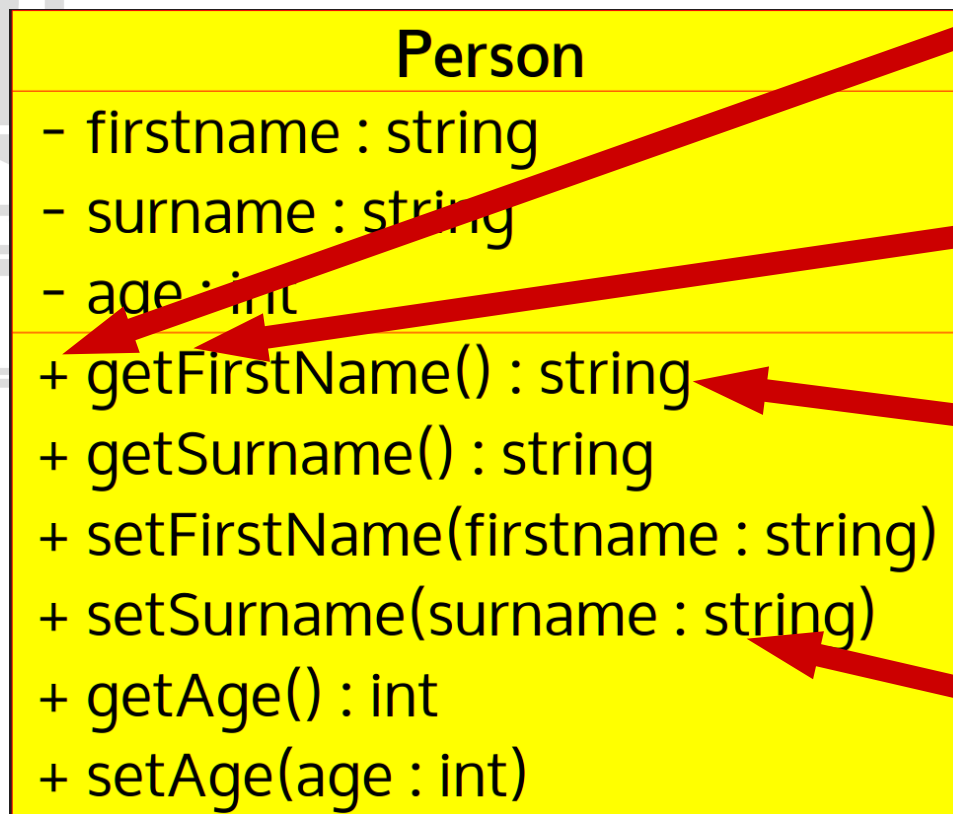

Type

# Class Diagrams

- The methods in class diagrams only show the *headers*. They do not show the logic.
- For each method the class diagrams show:
  - Name
  - Visibility
  - Arguments

# Class Diagram

- Class Diagram Methods

Visibility:  
- for private  
+ for public

Name

Return Type

Arguments (including  
types)

# Class API

- This is known as the *Class API*
- API stands for “Application Programmer Interface”
- Anyone using the class should only need an understanding of the API and not the *implementation* (how the method actually works)
- The programmer only needs to know the arguments and return type
- You will have seen this if you have ever looked up the documentation for a method in a programming language

# Class API

## Method Summary

static double	<a href="#">abs</a> (double a) Returns the absolute value of a double value.
static float	<a href="#">abs</a> (float a) Returns the absolute value of a float value.
static int	<a href="#">abs</a> (int a) Returns the absolute value of an int value.
static long	<a href="#">abs</a> (long a) Returns the absolute value of a long value.
static double	<a href="#">acos</a> (double a) Returns the arc cosine of a value; the returned angle is in the range 0.0 through $\pi$ .
static double	<a href="#">asin</a> (double a) Returns the arc sine of a value; the returned angle is in the range $-\pi/2$ through $\pi/2$ .
static double	<a href="#">atan</a> (double a) Returns the arc tangent of a value; the returned angle is in the range $-\pi/2$ through $\pi/2$ .
static double	<a href="#">atan2</a> (double y, double x) Returns the angle <i>theta</i> from the conversion of rectangular coordinates (x, y) to polar coordi
static double	<a href="#">cbrt</a> (double a) Returns the cube root of a double value.
static double	<a href="#">ceil</a> (double a) Returns the smallest (closest to negative infinity) double value that is greater than or equal to
static double	<a href="#">copySign</a> (double magnitude, double sign) Returns the first floating-point argument with the sign of the second floating-point argument.
static float	<a href="#">copySign</a> (float magnitude, float sign) Returns the first floating-point argument with the sign of the second floating-point argument.
static double	<a href="#">cos</a> (double a)

# Class API

## Method Summary

static double	<a href="#"><code>abs</code></a> (double a) Returns the absolute value of a double value.
static float	<a href="#"><code>abs</code></a> (float a) Returns the absolute value of a float value.
static int	<a href="#"><code>abs</code></a> (int a) Returns the absolute value of an int value.
static long	<a href="#"><code>abs</code></a> (long a) Returns the absolute value of a long value.
static double	<a href="#"><code>acos</code></a> (double a) Returns the arc cosine of a value; the returned angle is in the range 0.0 through $\pi$ .
static double	<a href="#"><code>asin</code></a> (double a) Returns the arc sine of a value; the returned angle is in the range $-\pi/2$ through $\pi/2$ .
static double	<a href="#"><code>atan</code></a> (double a) Returns the arc tangent of a value; the returned angle is in the range $-\pi/2$ through $\pi/2$ .
static double	<a href="#"><code>atan2</code></a> (double y, double x) Returns the angle <i>theta</i> from the conversion of rectangular coordinates (x, y) to polar coordi
static double	<a href="#"><code>cbrt</code></a> (double a) Returns the cube root of a double value.
static double	<a href="#"><code>ceil</code></a> (double a) Returns the smallest (closest to negative infinity) double value that is greater than or equal to
static double	<a href="#"><code>copySign</code></a> (double magnitude, double sign) Returns the first floating-point argument with the sign of the second floating-point argument.
static float	<a href="#"><code>copySign</code></a> (float magnitude, float sign) Returns the first floating-point argument with the sign of the second floating-point argument.
static double	<a href="#"><code>cos</code></a> (double a)

# PHP print API

**php** Downloads Documentation Get Involved Help

« parse\_str PHP Manual > Function Reference > Text Processing > Strings > String Functions

## String Functions

- addslashes
- addslashes
- bin2hex
- chop
- chr
- chunk\_split
- convert\_cyr\_string
- convert\_uuencode
- convert\_uuencode
- count\_chars
- crc32
- crypt
- echo
- explode
- fprintf
- get\_html\_translation\_table
- hebrew
- hebrevc
- hex2bin

## print

(PHP 4, PHP 5)

### Description

```
int print ( string $arg )
```

Outputs ***arg***.

***print*** is not actually a real function (it is a language construct) so

### Parameters

***arg***  
The input data.

### Return Values

Returns **1**, always.

### Examples

# C# File Reading Method

form

Connect

Downloads

Library

Samples

## File.ReadAllLines Method (String)

.NET Framework 4.5

[Other Versions](#) ▾

0 out of 3 rated this helpful - [Rate this topic](#)

Opens a text file, reads all lines of the file, and then closes the file.

**Namespace:** [System.IO](#)

**Assembly:** mscorlib (in mscorlib.dll)

### ▲ Syntax

C#

C++

F#

VB

```
public static string[] ReadAllLines(  
    string path  
)
```

#### Parameters

*path*

Type: [System.String](#)

The file to open for reading.

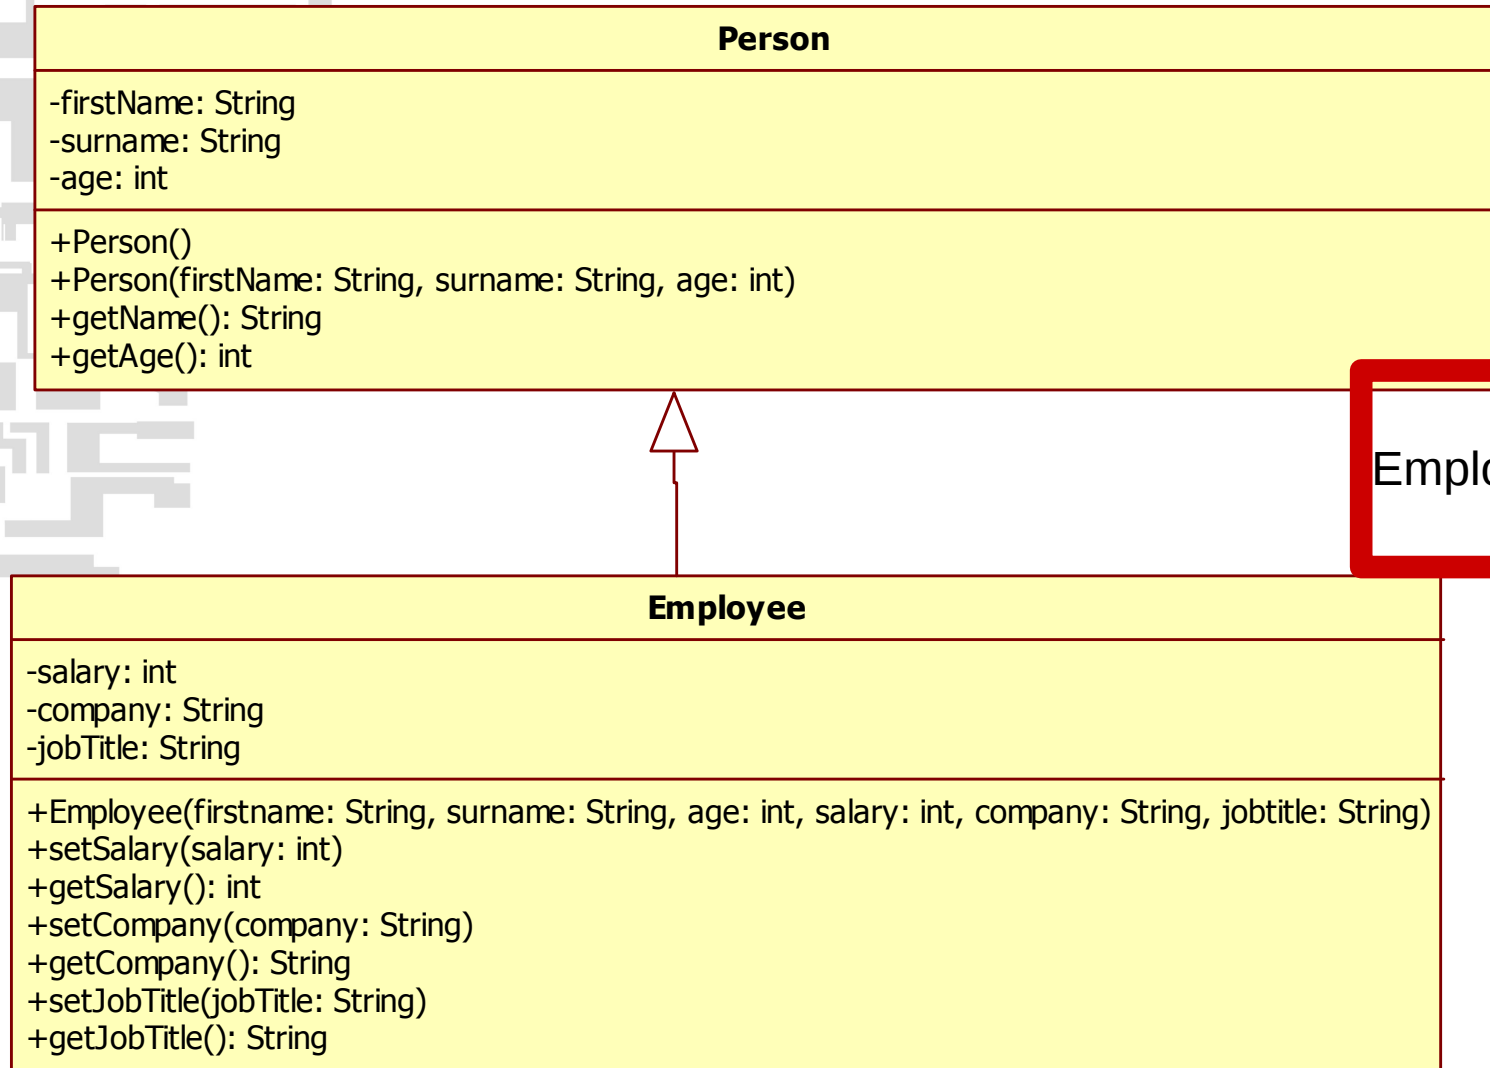

#### Return Value

(String)  
String,

# Class API

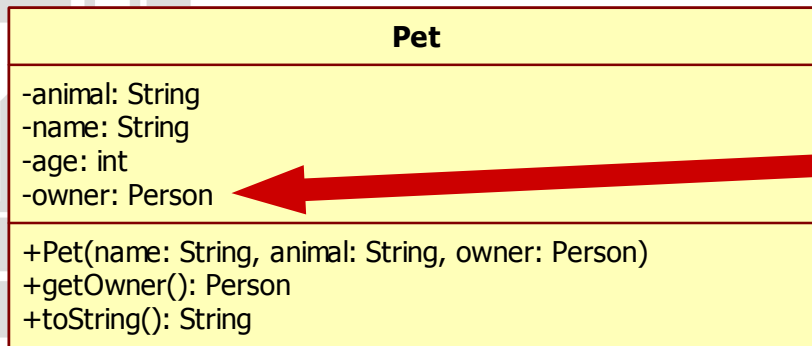

- None of these contain the *implementation* (the code in the method body)
- They only contain the method header:
  - The method name
  - Any arguments
  - The return value
- This is also what a UML Class diagram provides
- Anyone looking at the class API is not interested in the underlying code, only what it can be used for
- Do you need to know what the `System.out.println()` method does internally when you call it?

# Inheritance in UML

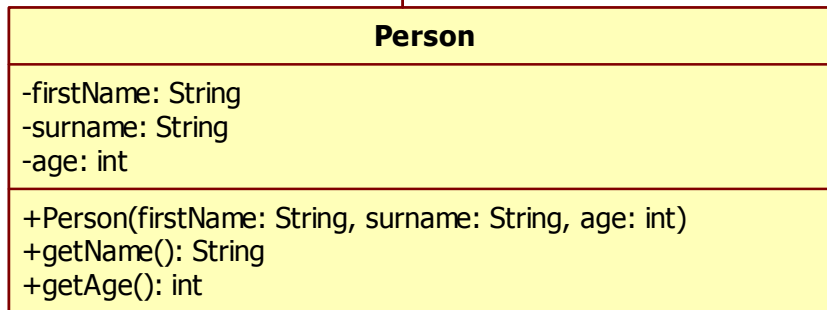

Employee extends Person

# Aggregation

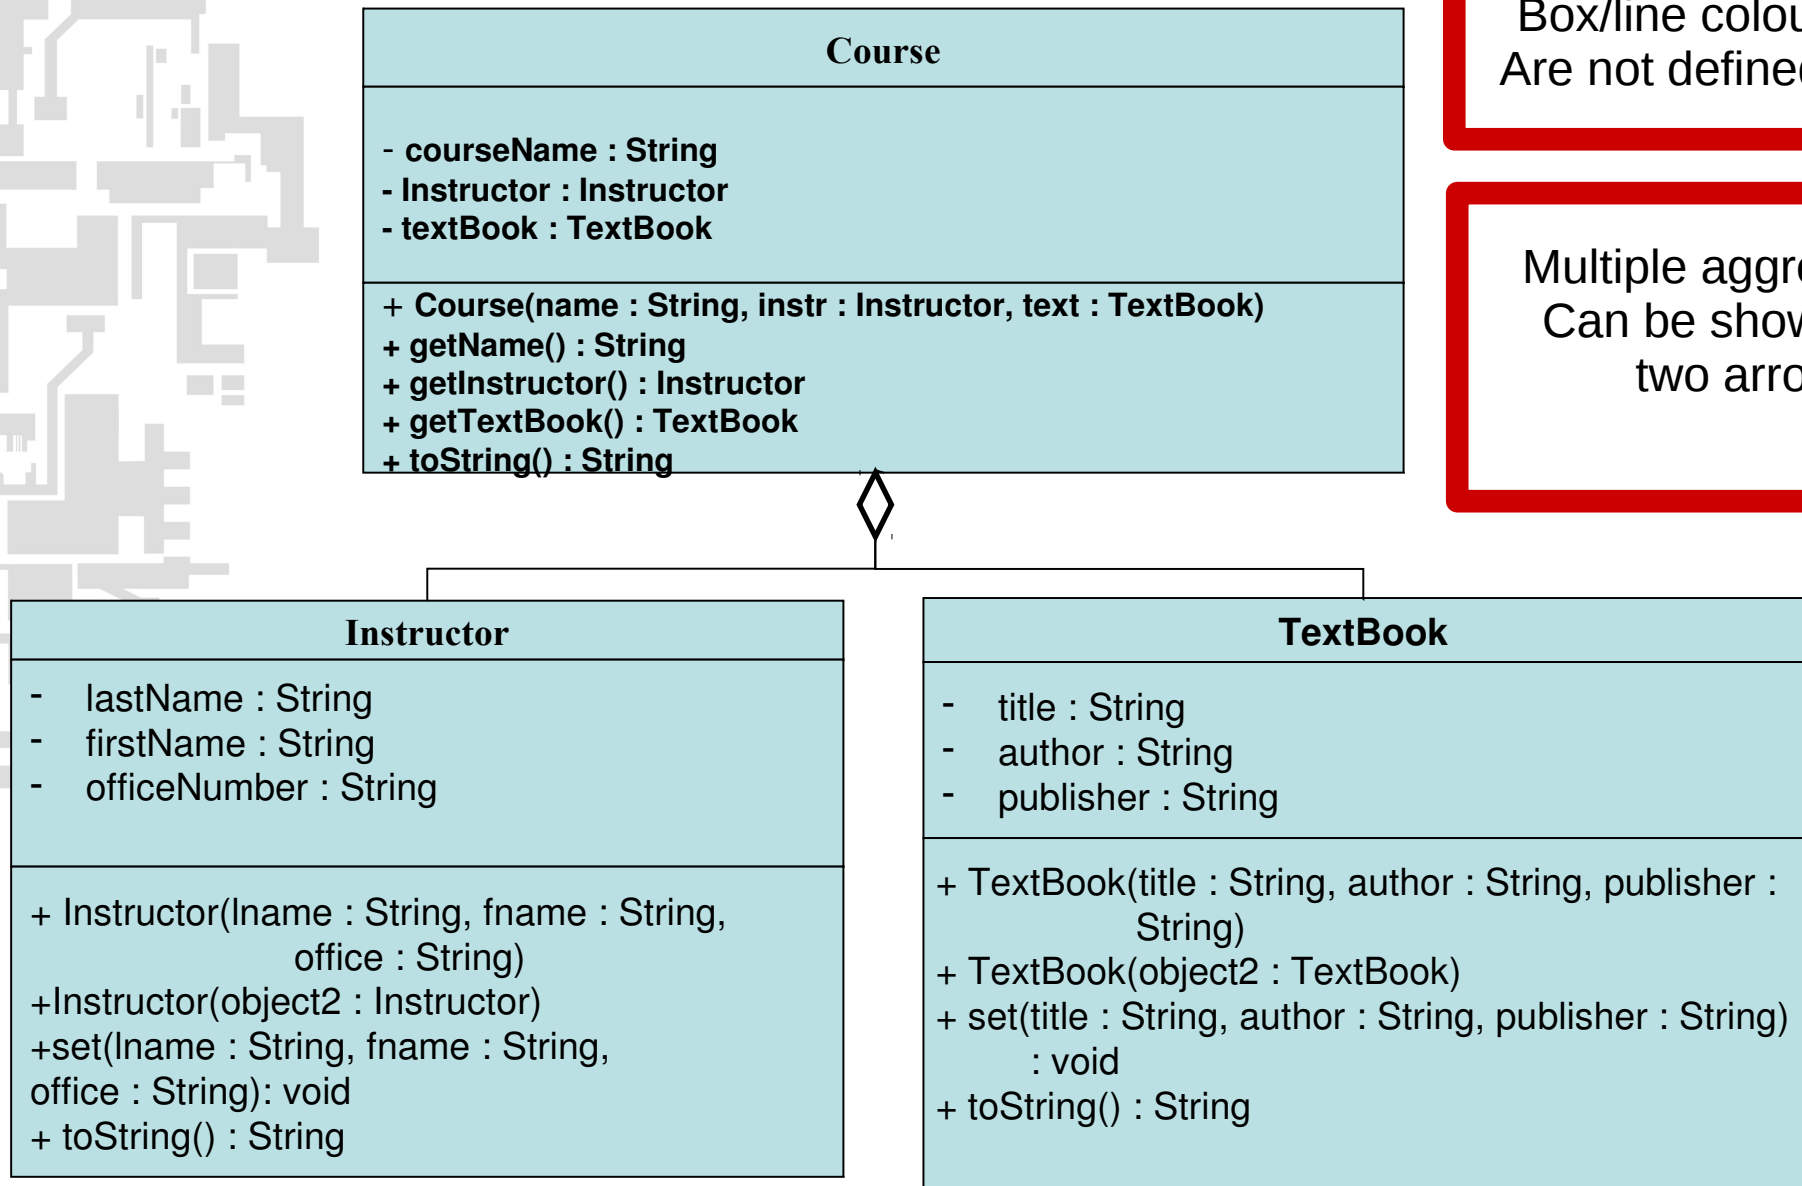

A pet has an owner of  
type Person

Aggregation uses a  
Diamond arrow

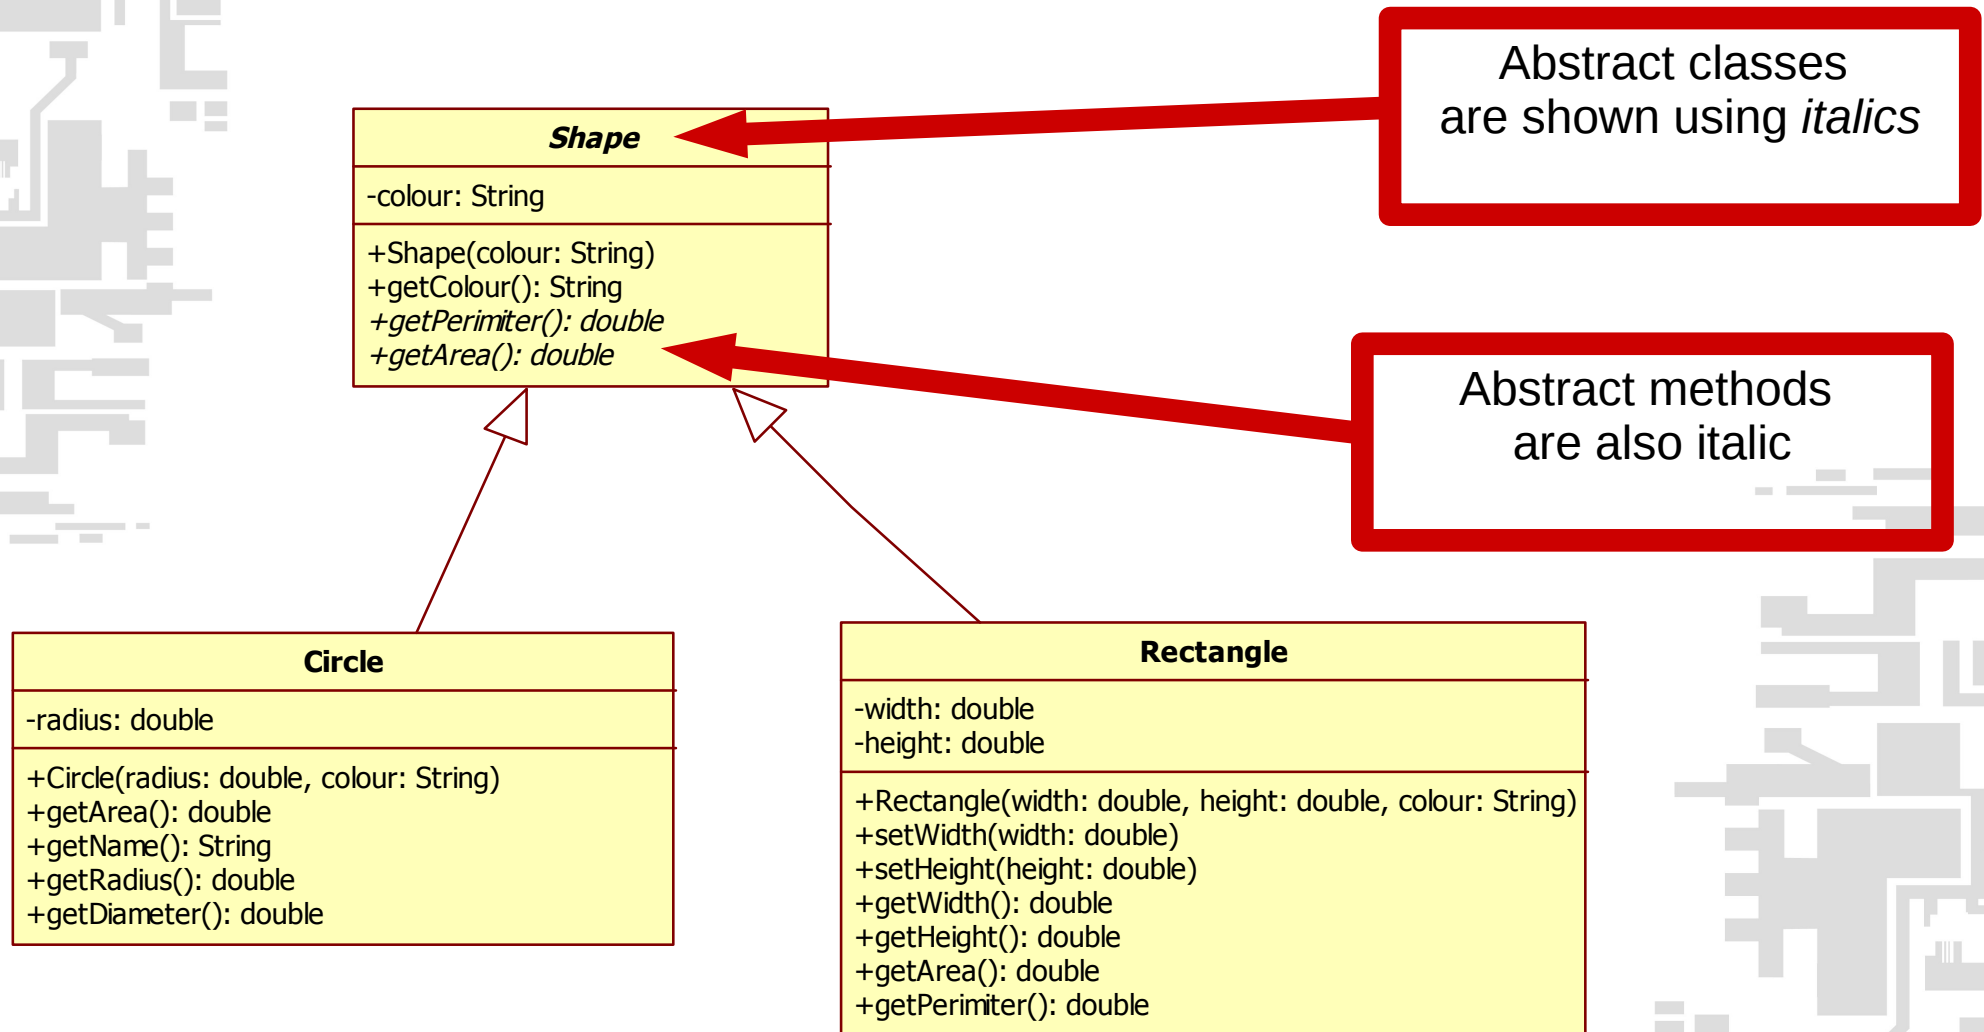

Box/line colours/fonts  
Are not defined in UML

Multiple aggregation  
Can be shown with  
two arrows

# Abstract Classes

# UML - Criticism

- UML is not used by all developers and faces some criticism
  - It's very easy for the diagram to get out of sync with the actual code. This is confusing for developers and reduces the usefulness of the diagrams
  - To overcome this, UML diagrams can be generated from the code.
  - However it's usually quicker to just look at the code!
